ACKNOWLEDGEMENT

The internship opportunity we had with AlmaMate info Tech was a great chance for learning and professional development. Therefore, we consider ourselves as very lucky as we were provided with an opportunity to be a part of it. We are also grateful for having a chance to meet so many wonderful people and professionals who led us through this internship period.

We express our deepest thanks to Mr. Shiv Shankar, Sr. Executive-Learning & Development at AlmaMate for taking part in useful decision & giving necessary advices and guidance and taking time out to hear, guide and keep us on the correct path and allowing us to carry out our project at their esteemed organization and extending during the training and all facilities to make project easier. We choose this moment to acknowledge his contribution gratefully.

It is our radiant sentiment to place on record our best regards, deepest sense of gratitude to Pranav sir(assistant professor) for their careful and precious guidance which were extremely valuable for our study both theoretically and practically.

We perceive this opportunity as a big milestone in our career development. We will strive to use gained skills and knowledge in the best possible way, and we will continue to work on their improvement, in order to attain desired career objectives. Hope to continue cooperation with all of you in the future.

INTRODUCTION

Project management system is a software that is required for analyzing keeping track and enhancing the project developing process.

Company has to go through a lot of project and has to handle a lot of team and member while working on a project making their way bulky and obsolete sometime when the work crosses over a limit of human boundation, in order to keep a track of a lot of project and stuff and to make them more efficient & economical, we requires a project management system and so does this project is all about keeping a track of lots of project and how do they function.

The function of project management system is to keep tracks of

- 1 No. of projects
- 2 Employee engaged in project
- 3 track of project
- 4 Invoice record and generation
- 5 Report and analysis

LIMITATONS OF CURRENT SYSTEM:-

Data redundancy

It means that same data fields appear in many different files and often in different formats. In manual system, it poses quite a big problem because the data has to be maintained in large volumes but in our system, this problem can be overcome by providing the condition that if the data entered is duplicate, it will not be entered, otherwise, updating will take place.

Difficulty in accessing the data

In manual system, searching information is time consuming but in our system, any information can be accessed by providing the primary key.

<u>Unsatisfactory security measures</u>

In manual system, no security measures were provided but in this system, password security has been provided. The person can access the system by providing the correct password otherwise he is denied the access.

These all can be solved while using and working through Salesforce, thus our project solves the problem of redundance, security and its quite easy to monitor data.

PROJECT MANAGEMENT

Project management is the discipline of initiating, planning, executing, controlling, and closing the <u>work</u> of a <u>team</u> to achieve specific goals and meet specific success criteria. A <u>project</u> is a temporary endeavor designed to produce a unique product, service or result with a defined beginning and end (usually time-constrained, and often constrained by funding or <u>deliverables</u>) undertaken to meet unique goals and objectives, typically to bring about beneficial change or added value. The temporary nature of projects stands in contrast with <u>business</u> as <u>usual</u> (or <u>operations</u>), which are repetitive, permanent, or semi-permanent functional activities to produce products or services. In practice, the <u>management</u> of these two systems is often quite different, and as such requires the development of distinct technical skills and management strategies.

The primary challenge of project management is to achieve all of the project goals within the given constraints. This information is usually described in a user or project manual, which is created at the beginning of the development process. The primary constraints are scope, time, quality and budget. The secondary and more ambitious challenge is to optimize the allocation of necessary inputs and integrate them to meet pre-defined objectives.

TOOLS AND TECHNOLOGIES USED: -

TECHNOLOGY USED: -

SALESFORCE

Salesforce helps you manage your customer relationships, integrate with other systems, and build your own applications.

Salesforce is one of the feature of cloud computing which help us to work in a more efficient and friendly manner.

It provide us a platform where we are no longer dependent on

Bulky software downloaded in our pc's, all we need is a system and internet.

Features of salesforce are

Manage Relationships and Data With Records

Much of your Salesforce data is stored in individual *records*, and organized within objects. For example, the Account object presents all of your account records. If the Acme company is one of your accounts, you'll have an account record for Acme.

• Find Information with Search

Salesforce search gives you the power to find information faster. Search is available via the Salesforce site, a Salesforce1 mobile app, or a custom search implementation built on the Salesforce platform.

• Run a Report

To run a report, find it on the Reports tab and click the report name. Most reports run automatically when you click the name. If you're already viewing a report, click Run Report to run it immediately or schedule a future run. In Lightning Experience, the Run Report button only appears after you save a report.

• Your Access to UI Elements, Records, and Fields

Your administrator can customize many different areas to secure your company's data. Users in Professional, Enterprise, Unlimited, Performance, and Developer Edition organizations can control other users' access to their data by sharing records individually with colleagues.

Q-WHAT IS SALESFORCE?

Salesforce helps you manage your customer relationships, integrate with other systems, and build your own applications.

Salesforce includes the following products and services.

Available in: SalesforceClassic

Salesforce Applications

Salesforce includes prebuilt applications (or "apps") for customer relationship management Your Salesforce edition (CRM) ranging from sales force automation to partner relationship management, marketing, determines which features and customer service, and functionality you can access.

Force.com Platform

The Force.com platform is the first platform as a service (PaaS), enabling developers to create and deliver any kind of business application entirely on demand and without software. The

platform also includes easy to use point-and-click customization tools to help you create solutions for your unique business requirements, without any programming experience.

Cloud A Salesforce name for a loose federation of features that help you accomplish certain types activities, such as

selling products, supporting your customers, or collaborating with your coworkers. Two common examples you'll come across are *Service Cloud* and *Sales Cloud*.

Cloud Computing

Technology that enables Internet-based services that let you sign up and log in through a browser. Salesforce delivers its service in the cloud. Other familiar cloud computing services include Google Apps and Amazon.com.

Software as a Service (SaaS)

Software delivered not by traditional means (such as on disk) but in the cloud, as a service. There's nothing to download or install, and updates are automatic.

Trust

A Salesforce term for its company-wide commitment to building and delivering the most secure, fast, and reliable cloud-based service available.

Created to enhance customer success, trust.salesforce.com is a systems status website giving Salesforce customers and the community access to real-time and historical system performance information and updates, incident reports and maintenance schedules across all its key system components. trust.salesforce.com is free to all members of the Salesforce community.

App

Short for *application*. A collection of components such as tabs, reports, dashboards, and Visualforce pages that address specific business needs. Salesforce provides standard apps, which you can customize, such as Sales and Call Center. You can customize the standard apps to

match the way you work.

Edition	One of several bundles of Salesforce products and services, each geared toward a different set of business needs. All Salesforce editions share the same look and feel, but they vary by feature, functionality, and pricing.		
Object	A definition of a specific type of information you can store in Salesforce. For example, the Case object lets you store information about customer inquiries. For each object, your organization will have multiple, specific records.		
	Salesforce comes with lots of standard objects, but you can create custom objects, as well.		
Organization	A deployment of Salesforce that has a defined set of licensed users. Your organization includes all of your data and applications.		

Term Definition

\mathbf{r}					1
R	\sim	1	\sim	*	~
\mathbf{r}	_				

A collection of fields that store information about a specific item of a specific type (represented by an object), such as a contact, an account, or an opportunity. For example, you might have a contact record to store information about Joe Smith, and a case record store information about his training inquiry.

Release

Salesforce releases new products and features three times per year, and releases are identified by season—Winter, Spring, and Summer—along with the calendar year. *Example:* Winter '15.

For every Salesforce release, the Salesforce release notes include new features and products that are generally available or in beta release, plus all changes to existing features and products. You can find the release notes when you search for "Release Notes" in the Salesforce Help.

Salesforce

The name of the Salesforce cloud computing CRM service.

Salesforce

The company name.

The Salesforce features listed here are those that are also available in Database.com. The features are organized by general product area. Some features are only available through the API. These are noted where they appear.

SCOPE OF PROJECT

- Manage Client Projects.
- Track Invoices.
- Track Bills of a Project.
- Track no. of Days Worked on Project.
- Track no. of Hours Worked on Project.
- Create Invoice to be Send to Client.
- Track the Balance Amount Left on Project.
- Approval of project via hierarchy.
- Backup of Data.

<u>S.R.S</u>

A software requirements specification (SRS) is a comprehensive description of the intended purpose and environment for <u>software</u> under development. The SRS fully describes what the software will do and how it will be expected to perform.

An SRS minimizes the time and effort required by developers to achieve desired goals and also minimizes the development cost. A good SRS defines how an <u>application</u> will interact with system <u>hardware</u>, other programs and human users in a wide variety of real-world situations. Parameters such as operating speed, <u>response</u> time, <u>availability</u>, <u>portability</u>, maintainability, <u>footprint</u>, security and speed of recovery from adverse events are evaluated. Methods of defining an SRS are described by the <u>IEEE</u>(Institute of Electrical and Electronics Engineers) specification 830-1998.

System development life cycle

Definition

A software process model or a software engineering is an abstract representation of a software process. It is a software development strategy that encompasses the process, methods and tools layers plus the generic phases namely definition phase, development phase and support phase. A process model is chosen based on the nature of the project and application, the methods and tools to be used and the controls and deliverables that are required.

Spiral Model

The spiral model, also known as the spiral lifecycle model, is a systems development lifecycle model used in information technology (IT). This model of development combines the features of the prototyping model and the waterfall model. The spiral model is favored for large, expensive, and complicated projects.

The steps in the spiral model iteration can be generalized as follows:

- 1. The system requirements are defined in as much detail as possible. This usually involves interviewing a number of users representing all the external or internal users and other aspects of the existing system.
- 2. A preliminary design is created for the new system. This phase is the most important part of "Spiral Model". In this phase all possible (and available) alternatives, which can help in developing a cost effective project are analyzed and strategies to use them are decided. This phase has been added specially in order to identify and resolve all the possible risks in the project development. If risks indicate any kind of uncertainty in requirements, prototyping may be used to proceed with the available data and find out possible solution in order to deal with the potential changes in the requirements.
- 3. A first prototype of the new system is constructed from the preliminary design. This is usually a scaled-down system, and represents an approximation of the characteristics of the final product.
- 4. A second prototype is evolved by a fourfold procedure:
- 1. Evaluating the first prototype in terms of its strengths, weaknesses, and risks.
 - 2. Defining the requirements of the second prototype.
 - 3. Planning and designing the second prototype.
 - 4. Constructing and testing the second prototype.

ANALYSIS

1. REQUIREMENT ANALYSIS:

Requirements are a feature of a system or description of something that is capable of doing in order to fulfill the system's purpose. It provides the appropriate mechanism for understanding what the customer wants, analyzing the needs, assessing feasibility, negotiating a solution, specifying the solution unambiguously, validating the specification and managing the requirements as they are translated into an operational system. Requirement Analysis is a task done under software engineering and software design. While requirements engineering specifies software s operational characteristics i.e. function, data behavior, indicates software s interface constraints, requirements analysis let the software engineer (called analysis) to refine the software allocation and construct models of data, functional and behavioral domains. Moreover, requirements analysis provides software developer with a representation of data, function and behavior that can be converted to data, architectural, interface and component level designs. At last, we can say that the requirement specification makes available, the developer and the customer, a means to assess quality, once the software has been built.

Software requirements analysis can be categorized into four areas of effort, as follows-

Evaluation and synthesis, Modeling, Specification, Review

The analyst starts with the studies of system specification and the software project plan. It is then important to understand the software in a system context. Also, the review of the software scope, used to generate planning estimate, is necessary. Next, communication for analysis must be established, so as to ensure problem recognition. The reason behind is to recognize the basic problem elements perceived by customer.

The next major area of effort for analysis is problem evaluation and solution synthesis. The engineer (or analyst) must define all data objects that are extremely observable. He must evaluate the content and flow of information. Also, he must define and describe all software functions, understand software behavior in the context of the system affected

events, establish the characteristics of system interface, and uncover additional design constraints.

After evaluating the current problems and desired information (i.e., input and output), the engineer and analyst synthesizing one or more solutions. Initially, the data objects, processing functions and the system behavior are defined in detail. Once establishing this information, the analyst then considers basic architectures for implementation. Thus the process of evaluation and synthesis proceeds until both analyst and the customer are sure that software can be adequately specified for subsequent development steps.

During the evaluation and synthesis activity, the analyst creates the system model so as to better understand data and control flow, functional processing, operational behavior and the information content. The model provides a base for software design and the creation of specifications for the software.

2. REQUIREMENT SPECIFICATIONS:

A Software Requirements Specification (SRS) is a complete description of the behavior of the system to be developed. It includes a set of use case that describes all the interactions that the users will have with the software. Use cases are also known as Functional Requirements. Non-Functional Requirements are requirements which impose constraints on the design or implementation (such as performance requirements, quality standards, or design constraints).

i. FUNCTION

REQUIREMENTS Performance

Requirements

User Satisfaction: - The system is such that it stands up to the user expectations.

Response Time: -The response of all the operation is good. This has

been made possible by careful programming.

Error Handling: - Response to user errors and undesired situations has been taken care of to ensure that the system operates without halting.

Safety and Robustness: - The system is able to avoid or tackle disastrous action. In other words, it should be foul proof. The system safeguards against undesired events, without human intervention.

Portable: - The software should not be architecture specific. It should be easily transferable to other platforms if needed.

User friendliness: - The system is easy to learn and understand. A native user can also use the system effectively, without any difficulties.

Design constraint

There are a number of factors in the client's environment that may restrict the choices of a designer. Such factors include standards that must be followed, resource limits, operating environment, reliability and security requirements and policies that may have an impact on the design of the system. An SRS (Software Requirements Analysis and Specification) should identify and specify all such constraints.

Standard Compliance: - This specifies the requirements for the standards the system must follow. The standards may include the report format and accounting properties.

Hardware Limitations:- The software may have to operate on some existing or predetermined hardware, thus imposing restrictions on the design. Hardware limitations can include the types of machines to be used, operating system available on the system, languages supported and limits on primary and secondary storage.

Reliability and Fault Tolerance: - Fault tolerance requirements can place a major constraint on how the system is to be designed. Fault tolerance requirements often make the system more complex and expensive. Requirements about system behavior in the face of certain kinds of faults are specified. Recovery requirements are often an integral part here, detailing what the system should do I some failure occurs to ensure certain properties. Reliability requirements are very important for critical applications.

Security: - Security requirements are particularly significant in defense systems and database systems. They place restrictions on the use of certain commands, control access to data, provide different kinds of

access requirements for different people, require the use of passwords and cryptography techniques and maintain a log of activities in the system.

ii. HARDWARE REQUIREMENTS

For the hardware requirements the SRS specifies the logical characteristics of each interface b/w the software product and the hardware components. It specifies the hardware requirements like memory restrictions, cache size, the processor, RAM size etc... those are required for the software to run.

Minimum Hardware Requirements

Processor Pentium IIIHard disk drive 40 GBRAM 128 MBCache 512 kb

Preferred Hardware Requirements

Processor Pentium IVHard disk drive 80 GBRAM 256 MBCache 512kb

iii. SOFTWARE REQUIREMENTS

Any window based operating system with DOS support are primary requirements for software development. Windows XP, FrontPage and dumps are required. The systems must be connected via LAN and connection to internet is mandatory.

It should also contain compatible browsers. An account or license of Salesforce platform is necessary.

Other requirements:

Software should satisfy following requirements as well:-

SECURITYPORTABILITYCORRECTNESSEFFICIENCYFLEXIBILT YTESTABILTYR EUSABILTY

iv. NON-FUNCTIONAL REQUIREMENTS

Security:

The system use SSL (secured socket layer) in all transactions that include any confidential customer information. The system must automatically log out all customers after a period of inactivity. The system should not leave any cookies on the customer's computer containing the user's password. The system's back-end servers shall only be accessible to authenticated management.

Reliability:

The reliability of the overall project depends on the reliability of the separate components. The main pillar of reliability of the system is the backup of the database which is continuously maintained and updated to reflect the most recent changes. Also the system will be functioning inside a container. Thus the overall stability of the system depends on the stability of container and its underlying operating system.

Availability:

The system should be available at all times, meaning the user can access it using a web browser, only restricted by the down time of the server on which the system runs. A customer friendly system which is in access of people around the world should work 24 hours. In case of a of a hardware failure or database corruption, a replacement page will be shown. Also in case of a hardware failure or database corruption, backups ofthe database should be retrieved from the server and saved by the Organizer. Then the service will be restarted. It means 24 x 7 availability.

Maintainability:

A commercial database is used for maintaining the database and the application server takes care of the site. In case of a failure, a reinitialization of the project will be done. Also the software design is being done with modularity in mind so that maintainability can be done efficiently.

Supportability:

The code and supporting modules of the system will be well documented and easy to understand. Online User Documentation and Help System Requirements.

3. DESIGN PHASE

The design phase involves converting the informational, functional, and network requirements identified during the initiation and planning phases into unified design specifications that developers use to script programs during the development phase.

Program designs are constructed in various ways. Using a top-down approach, designers first identify and link major program components and interfaces, then expand design layouts as they identify and link smaller subsystems and connections. Using a bottom-up approach, designers first identify and link minor program components and interfaces, then expand design layouts as they identify and link larger systems and connections. Contemporary design techniques often use prototyping tools that build mock-up designs of items such as application screens, database layouts, and system architectures. End users, designers, developers, database managers, and network administrators should review and refine the prototyped designs in an iterative process until they agree on an acceptable design. Audit, security, and quality assurance personnel should be involved in their view and approval process. During this phase, the system is designed to satisfy the functional requirements identified in the previous phase. Since problems in the design phase could be very expensive to solve in the later stage of the software development, a variety of elements are considered in the design to mitigate risk. These include:

- Identifying potential risks and defining mitigating design features.
- Performing a security risk assessment. Developing a conversion plan to migrate current data to the new system.
- Determining the operating environment.
- Defining major subsystems and their inputs and outputs.
- Allocating processes to resources.
- Preparing detailed logic specifications for each software module.
 The result is a draft System Design Documentwhich captures the preliminary design for the system. Everything requiring user input or approval is documented and reviewed by the user. Once these documents have been approved by the Agency CIO and Business

Sponsor, the final System Design Document is created to serve as the Critical/Detailed Design for the system. This document receives a rigorous review by Agency technical and functional representatives to ensure thatit satisfies the business requirements. Concurrent withthe development of the system design, the Agency Project Manager begins development of the Implementation Plan, Operations and Maintenance Manual, and the Training Plan.

4. IMPLEMENTION PHASE

The development phase involves converting design specifications into executable programs.

Effective development standards include requirements that programmers and other project participants discuss design specifications before programming begins. The procedures help ensure programmers clearly understand program designs and functional requirements.

Programmers use various techniques to develop computer programs. The large transaction-oriented programs associated with financial institutions have traditionally been developed using procedural programming techniques. Procedural programming involves the line-by-line scripting of logical instructions that are combined to form a program. Effective completion of the previous stages is a key factor in the success of the Development phase.

The Development phase consists of:-

- Translating the detailed requirements and design into system components.
- Testing individual elements (units) for usability.
- Preparing for integration and testing of the IT system. Integration and Test Phase.

5. INTEGRATION AND TEST PHASE

Subsystem integration, system, security, and user acceptance testing is conducted during the integration and test phase. The user, with those responsible for quality assurance, validates that the functional requirements, as defined in the functional requirements document, are

satisfied by the developed or modified system. OIT Security staff assesses the system security and issue a security certification and accreditation prior to installation/implementation.

Multiple levels of testing are performed, including:-

- Testing at the development facility by the contractor and possibly supported by end users.
- Testing as a deployed system with end users working together with contract personnel.
- Operational testing by the end user alone performing all functions.

Requirements are traced throughout testing, a final Independent Verification & Validation evaluation is performed and all documentation is reviewed and accepted prior to acceptance of the system.

6. IMPLEMENTATION PHASE

This phase is initiated after the system has been tested and accepted by the user. In this phase, the system is installed to support the intended business functions. System performance is compared to performance objectives established during the planning phase. Implementation includes user notification, user training, installation of hardware, installation of software onto production computers, and integration of the system into daily work processes. This phase continues until the system is operating in production in accordance with the defineduser requirements.

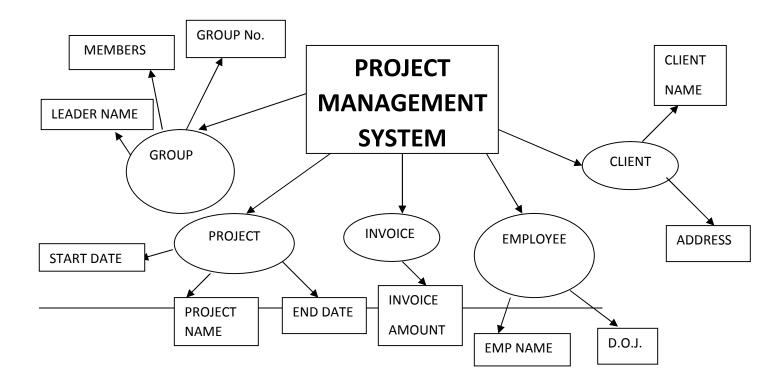

7. OPERATION AND MAINTENANCE PHASE

The system operation is ongoing. The system is monitored for continued performance in accordance with user requirements and needed system modifications are incorporated. Operations continue as long as the system can be effectively adapted to respond to the organization's needs. When modifications or changes are identified, the system may reenter the planning phase.

The purpose of this phase is to:-

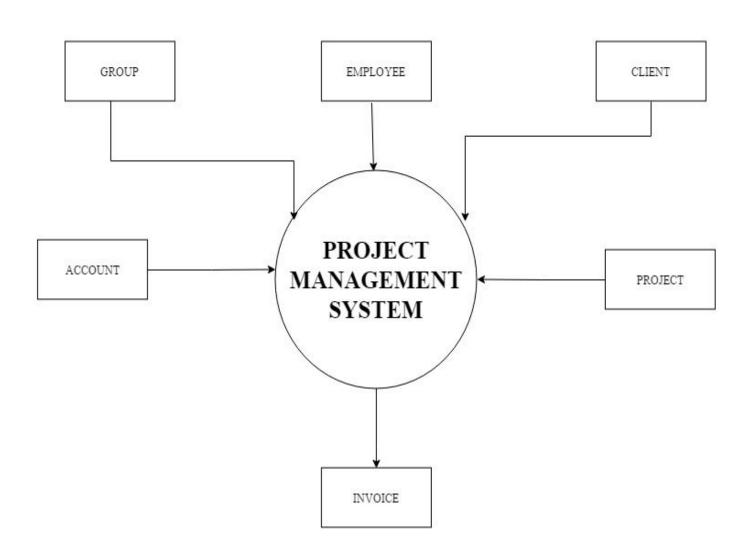

- Operate, maintain, and enhance the system.
- Certify that the system can process sensitive information.
- Conduct periodic assessments of the system to ensure the functional requirements continue to be satisfied.
- Determine when the system needs to be modernized, replaced, or retired.

LIMITATION

Limited user

Here we only got to work with a max of five user id thus restricting our scope of adding more departments or field in it. This limitation can be overcome by purchasing more license from salesforce.

Self tracking of previous client

We can not trackdown the previous client that have a relation with company.

Bill generation

In term of billing we could not extract a bill of past records.

Limited permission

The permission provided while working in salesforce software were limited

FUTURE SCOPE

The IT sector is growing rapidly so is the requirement of apps, with more upgradation and enhancement it will come on it. There will always be a project upcoming in the world, so is the need of managing it.

Hence the need of project management system is always there and will be always there in the market.
